

Conditioning & Stability (§12) (Lec3)

property of the math problem → properties of alg. used to solve it.

Problem is map $f: X \rightarrow Y$
problem input space
space of solns.

e.g. $f(x)$ could return 2x
return vector of roots of polynomial
given $x = \text{coeffs of poly.}$

a prob. Well-conditioned if perturbation δx in x causes 'small' pert $\delta f = f(x + \delta x) - f(x)$
Tone symb.

$$\text{Abs. condn} \# \quad \kappa = \hat{\kappa}(x) := \lim_{\delta \rightarrow 0} \sup_{\|\delta x\| \leq \delta} \frac{\|f(x + \delta x) - f(x)\|}{\|\delta x\|} \quad \text{abbr.} \quad \sup_{\delta x} \frac{\|f(x + \delta x) - f(x)\|}{\|\delta x\|}$$

express in derivatives: Jacobian $J(x)$ elements $\frac{\partial f_i}{\partial x_j}(x)$ As $\|\delta x\| \rightarrow 0$ we have $\delta f \approx J(x) \delta x$

$$\text{more useful is Rel. cond} \# \quad \kappa := \sup_{\delta x} \frac{\|f(x + \delta x) - f(x)\|}{\|\delta x\|} = \frac{\|J(x)\|_2}{\|f\|/\|x\|} \quad \text{important since computes rel. errors.}$$

$\kappa < 10^3$ well-cond'
 $\kappa \gg 10^3$ ill-cond

Basic operations

- $f(x) = x/2 \quad J = f' = 1/2 \quad \text{so } \kappa = 1$
- $f(x) = x^\alpha \quad J = f' = \alpha x^{\alpha-1} \quad \text{so } \kappa = \frac{\alpha x^{\alpha-1}}{x^\alpha/x} = |\alpha| \quad \ll 10^3 \text{ for reasonable power}$
- $f(x_1, x_2) = x_1 - x_2 \quad J = [1 \ -1] \quad \|J\|_2 = \sqrt{2} \quad \kappa = \frac{\sqrt{2} \sqrt{x_1^2 + x_2^2}}{|x_1 - x_2|} \rightarrow \infty \text{ as } x_1 \rightarrow x_2$
- $f(x) = \sin x \text{ for } x \approx 10^{100} \quad \|J\| \leq 1 \quad \text{but } \kappa = \frac{\|J\|_2}{\|\sin x\|/\|x\|} \geq |x| = \text{huge!}$

rel. cond. # depends here on argument x .

• finding poly roots is ill-cond.

• eigenvalues of non-symm. matrices e.g. $A = \begin{pmatrix} 1 & 10^3 \\ 1 & 1 \end{pmatrix}$

$$\lambda = \{1, 13\}$$

$$\|x\| = 10^3$$

$$\|f\| \approx 1$$

but $\kappa = 1$ (if $A^k = A$)

$$\lambda = \{0, 23\}$$

Mat-mult.

$$f(x) = Ax \quad A \in \mathbb{C}^{m \times m}$$

$$\kappa = \|A\| \cdot \frac{\|x\|}{\|Ax\|} \quad \text{if } A \text{ sq., nonsing.} \leq \|A^{-1}\| \quad \text{why?}$$

$$\text{so } \kappa \leq \|A\| \|A^{-1}\|$$

$$\|A^{-1}Ax\| \leq \|A^{-1}\| \cdot \|Ax\|$$

equality if $x = v_m$. defn of matrix 2-norm.

If A nonsing. then solving $Ax = b$ is $f(b) = A^{-1}b$. Replace A by A^{-1} makes $\kappa \leq \|A^{-1}\| \|A\|$

We call $\|A\| \|A^{-1}\| =: \kappa(A)$ cond# of matrix A . $= \frac{\sigma_1}{\sigma_m} = \text{eccentricity of hyperellipse.}$ equality if $x = u$, (PTO).

What if A is perturbed instead of b ?

$$(A + \delta A)(x + \delta x) = b$$

$$Ax + \delta Ax + A\delta x + \delta A\delta x = b$$

$$\text{so } \|\delta x\| \leq \|A^{-1}\| \|\delta A\| \|x\| \quad \text{v. small.}$$

Thm: $\frac{\|\delta x\|}{\|\delta A\| \|A\|} \leq \|A^{-1}\| \|A\| = \kappa(A)$

OPENING:

since A, b stored to e.g. 16 digits, expect to lose $\log_{10} \kappa(A)$ digits in acc. of x .
Now prove.

Let δA be a small perturbation of A , δb a small perturbation of b .

Want to show $\|x - \tilde{x}\| \leq \kappa(A) \|\delta A\| \|x\| + \|\delta b\| / \|A\|$

Let $\tilde{x} = A^{-1}b$ be the solution of $(A + \delta A)\tilde{x} = b$ and let $x = A^{-1}(b + \delta b)$ be the solution of $(A + \delta A)x = b + \delta b$.

Then $(A + \delta A)x = b + \delta b$ and $(A + \delta A)\tilde{x} = b$ so $(A + \delta A)x - (A + \delta A)\tilde{x} = \delta b$.

So $(A + \delta A)x - (A + \delta A)\tilde{x} = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

So $(A + \delta A)(x - \tilde{x}) = \delta b$ and $(A + \delta A)(x - \tilde{x}) = \delta b$ so $(A + \delta A)(x - \tilde{x}) = \delta b$.

(Lec 3)

Floating pt.

$x \in \mathbb{R}$ digital rep: finite # bits \Rightarrow finite subset F of \mathbb{R} \Rightarrow must be $\{\text{lowest} \& \text{highest}\} \rightarrow 10^{+308}$ gaps.
 in IEEE double prec.

e.g. $[1, 2]$ is set $\{1, 1 + 2^{-52}, 1 + 2 \cdot 2^{-52}, \dots, 2\}$
 $(2, 4)$ is twice these
 relative gap $2 \cdot 2 \times 10^{-16}$ never exceeded. (unstable)
 however poor alg. can cause this to dominate.

formally, base $\beta = 2$ precision $t = 53$ set $F = \{0, \pm \frac{m}{\beta^e} \beta^e, \pm \text{Inf}, \text{NaN}\}$ than members of \mathbb{R} . $\beta^{t-1} \leq m < \beta^t$ mantissa (so m/β^e in $[\beta, 1)$) $e \in \mathbb{Z}$ exponent(we ignore 'over/under-flow' that there's a largest $|e|$)NB $F = \beta F$ self-similar. $\epsilon_{\text{mach}} = \frac{1}{2} \beta^{1-t}$ is logit relative gap, ie $\forall x \in \mathbb{R} \exists x' \in F$ st $|x - x'| \leq \epsilon_{\text{mach}} x$

{}

IEEE double prec, $\epsilon_{\text{mach}} = 2^{-53} \approx 1.1 \times 10^{-16}$

Arithmetic

let $\oplus \ominus \otimes \oslash$ be analogs of $+ - \times \div$ except done by machine

limited relative err.

it could hold that $x \otimes y = f(x \times y)$ but all we need is weaker prop: Fund. axiom of floating pt: $\forall x, y \in F \exists \varepsilon$ with $|\varepsilon| \leq \epsilon_{\text{mach}}$ st. $x \otimes y = (1+\varepsilon)(x \times y)$ turns out for C arith, ϵ_{mach} can be replaced by $2^{5/2} \epsilon_{\text{mach}}$, similar. ie rel. err. at most ϵ_{mach} .

Mark Tuckerman: conditioning & roundoff to get stability.

SVD of vander(50): check its σ_j 's $\rightarrow \sigma_1 \uparrow 10^{16}$ computing σ_j 's is stable but back error you can do is $\sigma_1 \cdot \epsilon_{\text{mach}}$.
 $\epsilon_{\text{math.}(\sigma_j)} \rightarrow j$. \Rightarrow when $\sigma_m < \sigma_1 \epsilon_{\text{mach}}$, true rank cannot be determined.

Lec 3

M116

- conclude w/ bkw st. of A\bar{b} via SVD.
- or via Gauss elim w/ partial pivot. for m=n.
- or QR (Thm. 16-2).

(lect 4)

Stability (§14): getting (right) answer even if not exact

fix: problem $f: X \rightarrow Y$ eg. $y = \sin(x)$ or y is soln. to $Ay = b$ (here x data' is A, b).
floating pt. system:
algorithm for f , also map $X \rightarrow Y$.

data $x \rightarrow$
round to $\tilde{f}(x) \rightarrow$
call $\tilde{f}(x) \rightarrow$ apply alg.

Relative error of computation $\frac{\|\tilde{f}(x) - f(x)\|}{\|f(x)\|}$

← alg. good if this is $O(\varepsilon_{\text{mach}})$ ^{on the order of} eg. $10^2 \varepsilon_{\text{mach}}$ ok.
skip formally: $O(\varepsilon_{\text{mach}})$ means $\leq C\varepsilon_{\text{mach}}$ as $\varepsilon_{\text{mach}} \rightarrow 0$
for some C , uniformly over all data $x \in X$

Defns:

Alg. stable if $\forall x \in X$

$$\frac{\|\tilde{f}(x) - f(\tilde{x})\|}{\|f(x)\|} = O(\varepsilon_{\text{mach}}) \quad \text{for some } \tilde{x} \text{ w/ } \frac{\|\tilde{x} - x\|}{\|x\|} = O(\varepsilon_{\text{mach}})$$

nearly right ans. to nearly right qu.

Strongly: Backward stable

$$\tilde{f}(x) = f(\tilde{x}) \quad \text{for some } \tilde{x}, \quad \frac{\|\tilde{x} - x\|}{\|x\|} = O(\varepsilon_{\text{mach}})$$

exactly right ans to nearly right qu.

Eg. is \oplus bkw stable?

problem is $f(x_1, x_2) = x_1 - x_2$
alg is $\tilde{f}(x_1, x_2) = f_1(x_1) \oplus f_2(x_2)$ ⁼ for $|x_1|, |x_2| \leq \varepsilon_{\text{mach}}$
 $= [x_1(1+\varepsilon_1) - x_2(1+\varepsilon_2)](1+\varepsilon_3) = x_1(1+\varepsilon_4) - x_2(1+\varepsilon_5)$
ie exact for some data relatively close to x_1, x_2 . ^{for $\varepsilon_1, \varepsilon_2 \leq 2\varepsilon_{\text{mach}}$}
 $\varepsilon_3 = O(\varepsilon_{\text{mach}})$

is $f(x) = x \oplus 1$ bkw st?

$$\tilde{f}(x) = [x(1+\varepsilon_1) + 1](1+\varepsilon_2) = x(1+\varepsilon_3) + 1 \quad \text{but } \varepsilon_3 = O(\varepsilon_{\text{mach}}) + O(\varepsilon_{\text{mach}})$$

so not bkw st. as $x \rightarrow 0$; but is stable.

some algs are unsh

Take-home msg: algs in Matlab (Lapack, etc) for solving $Ay = b$ are bkn. stable.

$m=n$: QR is Thm 16.2.
nonsing. sq-sys. Gaussian elim w/ partial pivoting is, Ch. 22
(if avoid incredibly rare pathological matrices)

use to get understanding into quando how it happens to be bkn. inst. Red to small case $n=2$ and $m > n$:

least-squares soln: i.e. find x s.t. $\|Ax - b\|$ minimized.
is bkn st. via SVD: (Thm 19.4)
 $A = U \Sigma V^*$

$$x = A^T b = V^* \Sigma^{-1} U^* b$$

[See NLA
Ch. 6-23]

Note this means: The computed soln. \tilde{y}
to $Ay = b$ satisfies $(A + \delta A)\tilde{y} = b$

exactly, for some δA w/ $\frac{\|\delta A\|}{\|A\|} = O(\epsilon_{mach})$

A plays role of data x .
 y " " " " answer f .

However, $\frac{\|\tilde{y} - y\|}{\|y\|}$ may not be small, ie y not accurate!

Such is backward stability:
it's as good as could hope for!

How accurate is y ? Need acc. of any bkn-stable alg.

* Thm (15.1): if cond# is K for problem, and computer obeys floating point

$$\frac{\|f(\tilde{x}) - f(x)\|}{\|f(x)\|} = O(K(x) \epsilon_{mach}).$$

Pf: by defn. $f(x) = f(\tilde{x})$.
Defn of K :

(a) for some $\frac{\|\tilde{x} - x\|}{\|x\|} = O(\epsilon_{mach})$

(b)

$\frac{\|f(\tilde{x}) - f(x)\|}{\|f(x)\|} \leq \left(\frac{K}{\epsilon_{mach}} \right) \frac{\|\tilde{x} - x\|}{\|x\|}$ then sub. in (a) & (b)

* since not infinitesimal.

$\|f(\tilde{x}) - f(x)\| = O(K(x) \epsilon_{mach})$
so error norm is K times worse than ϵ_{mach} .
If $K \geq 10^{16}$ you lose all digits of y ! But, still it holds that $(A + O(\epsilon_{mach}))\tilde{y} = b$!

... but what does this mean? ...

Condition Number

method of computing condition number to code since basic

... depends on how well conditioned matrix is given by $\|A^{-1}\|$ or $\|A\|$

... good idea to make algorithm - not only to G. iteration to sub until no change

Least-Squares

... but often not enough to make it work
