

To prove that every group of order 4 is simple, we can use the following approach. A group is simple if it has no nontrivial normal subgroups, meaning it only has two trivial normal subgroups, the identity and the group itself.

Let  $G$  be a group of order 4. There are several cases to consider based on the possible group structures of  $G$ :

Case 1:  $G$  is isomorphic to  $Z_4$  (the cyclic group of order 4):

In this case,  $G$  is generated by a single element  $a$  such that  $a^4 = e$  (the identity element). Since  $G$  is cyclic, the subgroup generated by  $a$  is  $\{e, a, a^2, a^3\}$ . Any proper subgroup of  $G$  would have order less than 4, and therefore, it cannot be normal in  $G$ . Thus,  $G$  is simple.

Case 2:  $G$  is isomorphic to  $Z_2 \times Z_2$  (the direct product of two cyclic groups of order 2):

In this case,  $G$  has elements  $(a, b)$ , where  $a$  and  $b$  are generators of the two cyclic subgroups of order 2. The elements of  $G$  are  $\{(e, e), (a, e), (e, b), (a, b)\}$ , where  $(e, e)$  is the identity element.

Now, consider a subgroup  $H$  of  $G$ .  $H$  must contain the identity element  $(e, e)$  since it is a group. If  $H$  contains any of the elements  $(a, e)$  or  $(e, b)$ , then it will also contain their inverses, which are  $(a^3, e)$  and  $(e, b^3)$ , respectively. This is because in  $Z_2 \times Z_2$ , every element has order 2, and the only non-identity element in a cyclic group of order 2 is its own inverse. So,  $H$  must contain at least three elements:  $(e, e)$ ,  $(a, e)$ , and  $(e, b)$ .

Now, if  $H$  contains the element  $(a, b)$ , then it must also contain its inverse, which is  $(a^3, b^3)$ . However, the subgroup generated by  $(a^3, b^3)$  would also contain  $(e, e)$ ,  $(a, e)$ , and  $(e, b)$  since these are the products of  $(a, b)$  with  $(a^3, b^3)$ . Therefore,  $H$  would be the entire group  $G$ .

Since any subgroup  $H$  of  $G$  must either be the trivial subgroup  $\{e, e\}$  or the entire group  $G$ , there are no proper nontrivial subgroups of  $G$  that are normal. Thus,  $G$  is simple.

In both cases ( $Z_4$  and  $Z_2 \times Z_2$ ), we have shown that any group of order 4 is simple.

No, not every group of order 4 is simple. There are non-simple groups of order 4. The only two groups of order 4 are the cyclic group of order 4 (denoted as  $C_4$ ) and the Klein four-group (denoted as  $V_4$  or  $K_4$ ).

1. Cyclic Group of Order 4 ( $C_4$ ):
  - $C_4 = \{e, a, a^2, a^3\}$  where  $a^4 = e$ .
  - $C_4$  is a simple group because it has no nontrivial proper subgroups that are normal.
2. Klein Four-Group ( $V_4$  or  $K_4$ ):
  - $V_4 = \{e, a, b, c\}$  where  $a^2 = b^2 = c^2 = e$ , and  $ab = ba$ ,  $ac = ca$ ,  $bc = cb$ .
  - $V_4$  is not a simple group. It has three nontrivial proper subgroups:  $\{e, a\}$ ,  $\{e, b\}$ , and  $\{e, c\}$ . All of these subgroups are normal in  $V_4$ , and none of them are simple themselves.

So, while  $C_4$  is a simple group of order 4, the Klein four-group  $V_4$  is an example of a non-simple group of order 4. Therefore, not every group of order 4 is simple.
