

Last class, we introduced the derivative of a function of two variables through tangent planes. Let us now look at the point of view of partial derivatives.

Definition

The partial derivative of $f(x,y)$ with respect to x at (a,b) , denoted $f_x(a,b)$ is $f_x(a,b) = g'(a)$, where $g(x) = f(x, b)$ fixed.

Similarly, $f_y(a,b) = h'(b)$, where $h(y) = f(a, y)$.

Since g and h are defined as function of one variable, we can define their derivative in the usual way (with differentiation rules, or with the definition with the limit).

Notation

$$f_x(x,y) = \frac{\partial f}{\partial x} = \frac{\partial}{\partial x} f(x,y) = f_x$$

$$\text{and } f_y(x,y) = \frac{\partial f}{\partial y} = \frac{\partial}{\partial y} f(x,y) = f_y$$

Rule for finding partial derivatives of $f(x,y)$

- (i) To find f_x , regard y as a constant and differentiate $f(x,y)$ with respect to x .
- (ii) To find f_y , regard x as a constant and differentiate $f(x,y)$ with respect to y .

(2)

Example

If $f(x,y) = x^3 + x^2y^3 - 2y^2$, find $f_x(2,1)$ and $f_y(2,1)$.

Solution

$$f_x(2,1) = (3x^2 + 2xy^3)_{x=2,y=1} = 12 + 4 = 16$$

$$f_y(2,1) = (3x^2y^2 - 4y^2)_{x=2,y=1} = 12 - 4 = 8.$$

Example

If $f(x,y) = \sin\left(\frac{x}{1+y}\right)$, calculate $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$.

$$(i) \frac{\partial f}{\partial x} = \frac{1}{1+y} \cos\left(\frac{x}{1+y}\right) \text{ with the chain rule}$$

$$(ii) \frac{\partial f}{\partial y} = \frac{-x}{(1+y)^2} \cos\left(\frac{x}{1+y}\right)$$

Implicit definition

In one dimension a function $y=f(x)$ is defined implicitly if it is not defined by an equation with y isolated (on one side of the equation).

Example

The relation $x^2+y^2=25$ is the implicit definition of the two functions $y = \pm \sqrt{25-x^2}$

Implicit functions can be differentiated using the chain rule:

$$\frac{\partial}{\partial x} (x^2+y^2) = \frac{\partial}{\partial x} 25$$

$$\Rightarrow 2x + 2y \frac{\partial y}{\partial x} = 0$$

$$\Rightarrow \frac{\partial y}{\partial x} = \frac{-2x}{2y} = -\frac{x}{y}.$$

The same thing can be done for functions of two variables.

Example

Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ for $e^z = xyz$.

$$(i) \frac{\partial z}{\partial x} e^z = \frac{\partial z}{\partial x} \cdot xyz = y \frac{\partial z}{\partial x} xz' \stackrel{\text{product rule.}}{=} y(xz' + z)$$

On the other hand,

$$\frac{\partial z}{\partial x} e^z = e^z \frac{\partial z}{\partial x} = e^z z' \quad \text{Here, remember } z \text{ is a function of } x.$$

Thus, solving for z' , we get

$$\frac{\partial z}{\partial x} = z' = \frac{yz}{e^z - xy}.$$

$$(ii) \frac{\partial z}{\partial y} e^z = e^z \frac{\partial z}{\partial y}$$

$$\frac{\partial z}{\partial y} xyz = x \frac{\partial z}{\partial y} (yz) = x(z + y \frac{\partial z}{\partial y})$$

Hence,

$$\frac{\partial z}{\partial y} = \frac{xz}{e^z - xy}$$

Higher derivatives (second order, third derivative, etc.)

If f is a function of two variables, then so are f_x and f_y ,
so we can define second partial derivatives: $f_{xy}, f_{xx}, f_{yx}, f_{yy}$:

$$f_{xx} = (f_x)_x = \frac{\partial^2 f}{\partial x^2}$$

$$f_{yx} = (f_y)_x = \frac{\partial}{\partial x} \frac{\partial f}{\partial y}$$

$$f_{xy} = (f_x)_y = \frac{\partial}{\partial y} \frac{\partial f}{\partial x}$$

$$f_{yy} = (f_y)_y = \frac{\partial^2 f}{\partial y^2}$$

⚠ ∂^2 does not mean the square of the derivative.

Example

Find all the second partial derivatives of $f(x,y) = x^3 + x^2y^3 - 2y^2$.

On page 2, we already found that

$$f_x(x,y) = 3x^2 + 2xy^3 \quad \text{and} \quad f_y(x,y) = 3x^2y^2 - 4y$$

Therefore,

$$f_{xx}(x,y) = 6x + 2y^3$$

$$f_{yx}(x,y) = 6xy^2$$

$$f_{xy}(x,y) = 6xy^2$$

$$f_{yy}(x,y) = 6x^2y - 4.$$

Notice that $f_{xy} = f_{yx}$. This is not a coincidence...

Theorem (Clairaut, Yang, Euler, Schwartz...)

Let f be a function of x and y .

If f_{xy} and f_{yx} are continuous near (a,b) , then

$$f_{xy}(a,b) = f_{yx}(a,b).$$

Example

Let $f(x,y) = \ln(x+2y)$.

$$f_{xy} = \frac{\partial}{\partial x} \frac{2}{x+2y} = \frac{-2}{(x+2y)^2} \quad \text{and} \quad f_{yx} = \frac{\partial}{\partial y} \frac{1}{x+2y} = \frac{-2}{(x+2y)^2},$$

and indeed $f_{xy} = f_{yx}$.

Example

If $f(x,y) = x^3y^2 + \arcsin(x)$, find f_{xy} .

Using $f_{yx} = f_{xy}$, we get

$$f_{yx} = \frac{\partial}{\partial x} 2x^3y = 6x^2y = f_{xy}$$
